Q3. Call the summary() function on your results to get a sense of how many genes are up or down-regulated at the default 0.1 p-value cutoff.

#### summary(res)

```
out of 15975 with nonzero total read count
adjusted p-value < 0.1

At the default 0.1 p-value cutoff,

Up-regulated genes: 4351 genes

Down-regulated genes: 4399 genes

#### Volcano plot

```
plot(res$log2FoldChange, -log(res$padj))
```

#### Q4. Improve this plot by completing the below code, which adds color and axis labels

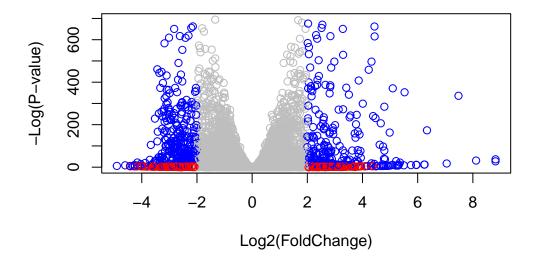

```
# Make a color vector for all genes
mycols <- rep("gray", nrow(res) )

# Color red the genes with absolute fold change above 2
mycols[ abs(res$log2FoldChange) > 2 ] <- "red"

# Color blue those with adjusted p-value less than 0.01

# and absolute fold change more than 2
inds <- (res$padj < 0.01) & (abs(res$log2FoldChange) > 2 )
mycols[ inds ] <- "blue"

plot( res$log2FoldChange, -log(res$padj), col=mycols, xlab="Log2(FoldChange)", ylab="-Log(</pre>

## Adding gene annotation

**Q5**. Use the **mapIDs()** function multiple times to add SYMBOL, ENTREZID and GENENAME annotation to our results by completing the code below.

```

Q8: What pathway has the most significant "Entities p-value"? Do the most significant pathways listed match your previous KEGG results? What factors could cause differences between the two methods?

According to Reactome, transport of small molecules has the most significant "Entities p-value", which doesn't match the KEGG results. GO is a dataset of genes without defining correlations between genes while KEGG defines the relationship between genes and metabolites.
